

"Advanced Database Administration II"

Assignment

Date: 15/06/2013

Bachelor In Information Technology

BIT – ITD420 Assignment

Scenario 1:

Restore and Recovery of a Whole Database

In this scenario, you have a current control file and SPFILE but all datafiles are damaged or lost. You must restore and recover the whole database.

The database has one read-only tablespace (*ITEM_TS*), which must be restored from backup but which does not need media recovery.

Write the commands and scripts needed to restore and recover the database when the current control file is available.

Note: make sure that the database is in the right mode before starting recovery steps, channels are allocated and configured, and the output of the recovery is successful.

Scenario 2:

Restore and Complete Recovery of Individual Tablespaces or Datafiles

In this scenario, the database is open, and some but not all of the datafiles are damaged. You want to restore and recover the damaged tablespace, while leaving the database open so that the rest of the database remains available.

Note: Determine Which Database Files to Restore or Recover (you can suppose the damaged files are *DF01*, *Df02* as an example), let RMAN choose the backups to use in restoring the tablespace and any needed incremental backups and logs from disk or tape, make sure that the database is in the right mode before starting recovery steps, channels are allocated and configured, and the output of the recovery is successful.

Assignment rules:

- 1. Students should work in groups of 3 at max.*
- 2. Students should write their names and identifiers clearly in the beginning of their assignments.*
- 3. Students must upload their assignments on Modle system.*
- 4. The files of the deliverables should be grouped in one zipped folder*
- 5. The zipped file should be named by the names of the students, like ASS_Jhussein_6103_Kjoumaa_6938.zip.*
- 6. The final date to accept assignments is 01/07/2013.*

Good luck.

Jamal Hussein, Dr. Kadan Aljoumaa
